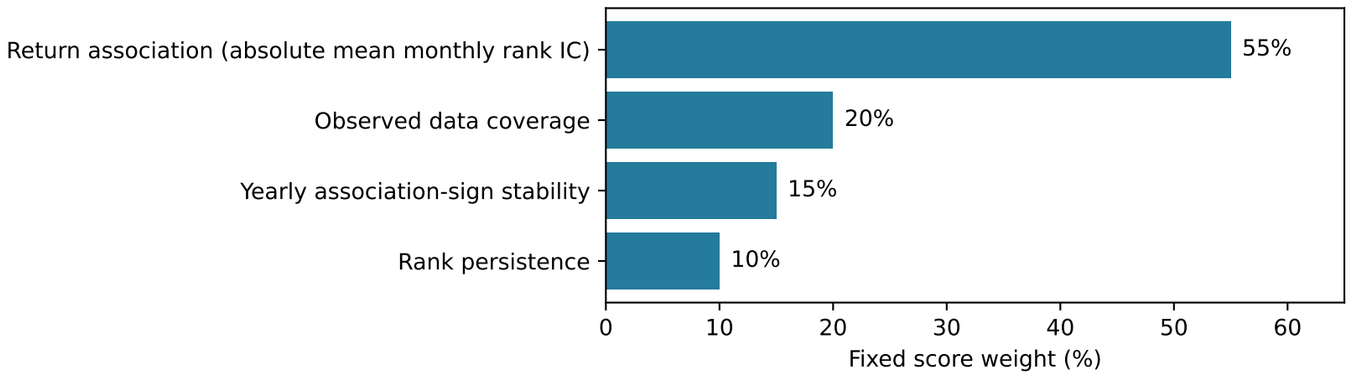
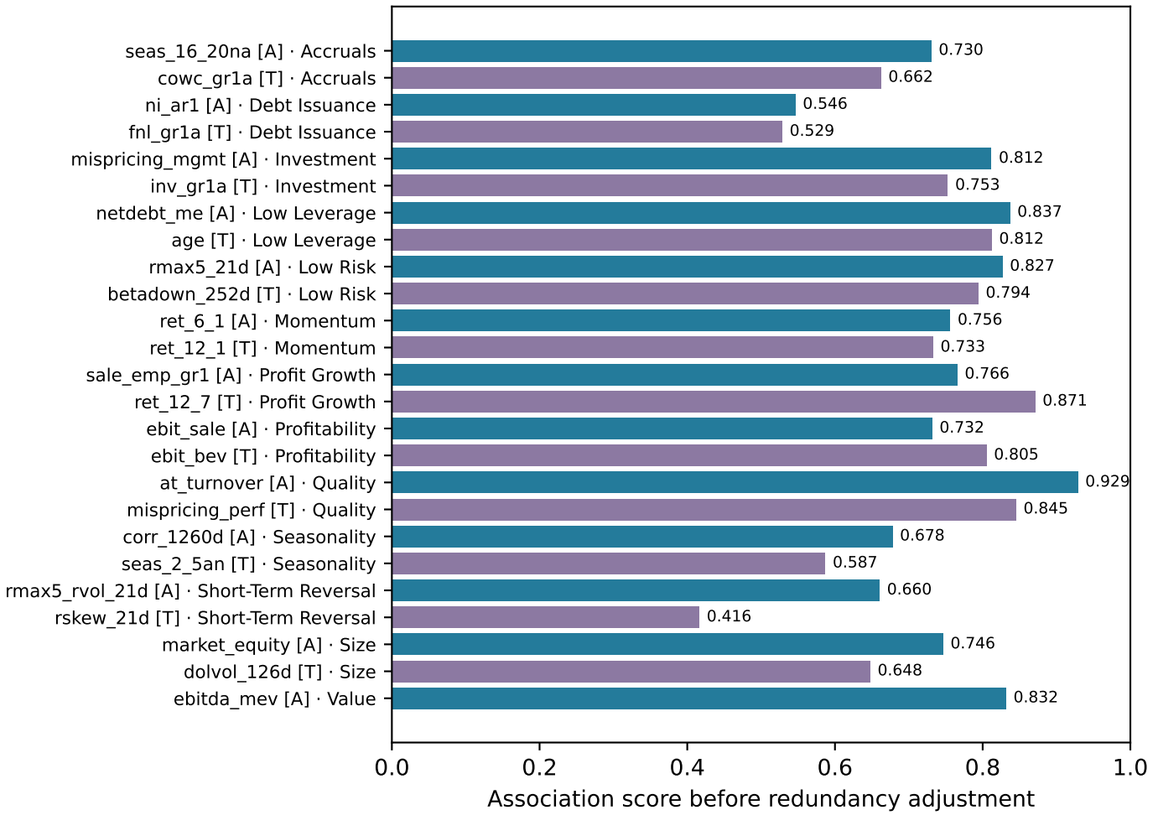
How the 50 characteristics were chosen

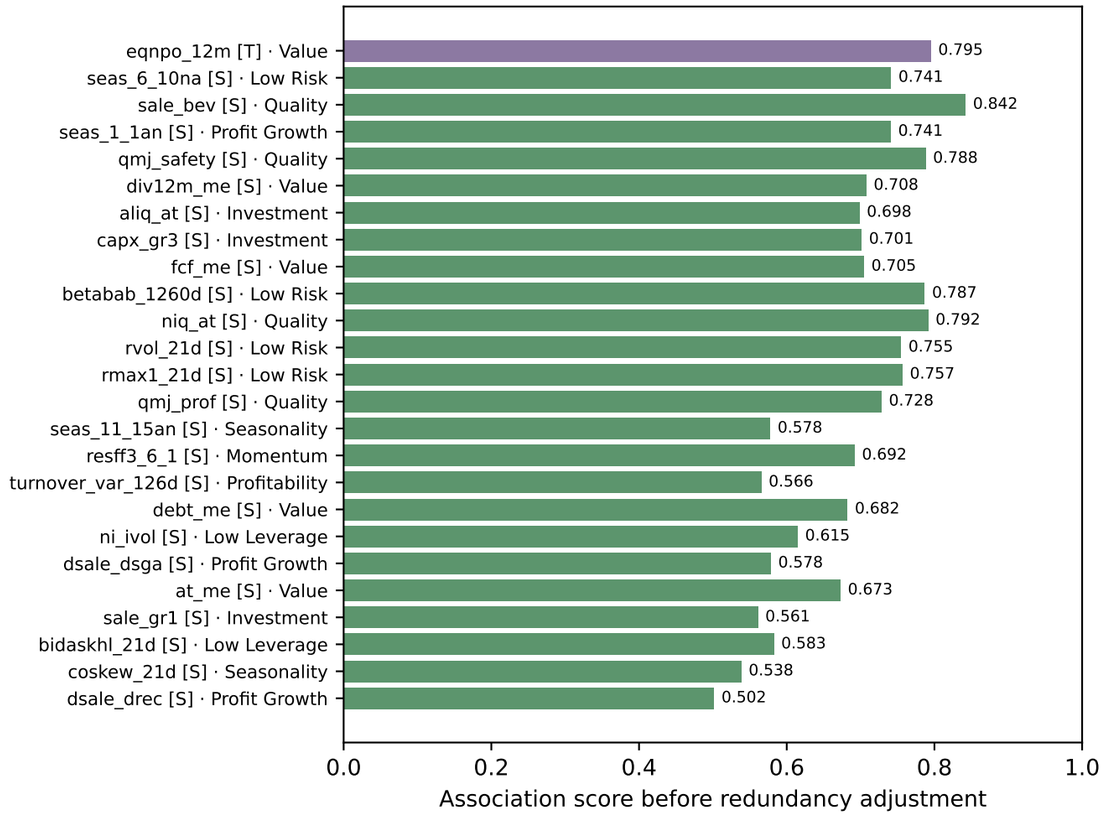


Selection rules

Score uses percentile ranks of the four measures.
Greedy priority = score + 0.02 for published label
− penalty × largest absolute correlation with chosen signals.

A: 13 published anchors (one per group)
T: 13 additions to reach two members per group
S: 24 further choices by score and redundancy





No ML fit. A/T/S explains inclusion, not model weights. Group quotas and correlation penalties mean the final 50 are not simply the 50 highest individual correlations.
